Bluetooth peripheral device driver dell

A peripheral device is any auxiliary device that connects to and works with a computer to put information in or out of it. The peripheral device can also be called an external peripheral, integrated peripheral, auxiliary components or an I/O (input/output) device. Logitech Mouse. Usually the word peripheral is used for a device outside the computer, such as a scanner, but devices that are physically located inside the computer are also technically peripheral devices. Peripheral devices add functionality to your computer, but they're not part of a major set of components like CPU, motherboard, and power supply. However, although they are often not directly included in the main function of the computer, this does not mean that they are not considered necessary components. For example, a desktop-style computer monitor does not technically help with computing and is not needed for the computer to be able to power and run programs, but it is necessary to actually use the computer. Another way to think about peripheral devices is not to work as standalone devices. The only way they work is when they're connected to and controlled by a computer. Peripherals are categorized as an input device or output device, and some function as both. Among these types of hardware are internal peripherals and external peripherals, any type of which can include input or output devices. Common internal peripherals that you will find in your computer include an optical disk, a video card, and a hard drive. In these examples, the disk drive is one example of a device that is both an input and an output device. The computer cannot use it only to read information stored on the disc (e.g. software, music, movies), but also to export data from computer to disk (as when burning DVDs). Network interface cards, USB expansion cards, and other internal devices that could connect to PCI Express or another type of port are all types of internal peripherals. Common external peripherals include devices such as mouse, keyboard, tablet pens, external hard drive, printer, projector, speakers, webcam, flash drive, media card readers and microphone. Anything you can connect to the outside of the computer, which usually does not work independently, can be called an external peripheral device. Some devices are considered peripheral devices because they can be detached from the primary function of the computer and can usually be removed fairly easily. This applies especially to external devices such as printers, external hard drives, etc. However, this is not always true, so although some devices can be considered internal on one system, they can just as easily be external peripheral devices on another. The keyboard is one great example. The desktop keyboard can be removed from the USB port and the computer will not stop working. It can be plugged in and removed as a time as much as you want and is a true example of an external peripheral device. However, the laptop keyboard is no longer considered an external device because it is definitely built-in and not easy to remove. This same concept applies to most laptop features, such as webcams, mice and speakers. Although most of these components are external peripherals on the desktop, they are considered internal on laptops, phones, tablets and other devices. Sometimes you'll see peripherals categorized as input devices and output devices depending on how they face your computer. For example, a printer provides output from a computer, so it is considered an output device, while another external peripheral device such as a webcam that sends data to a computer is called an input device.
